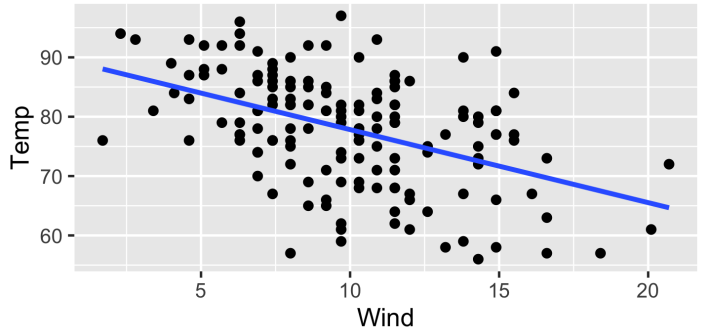
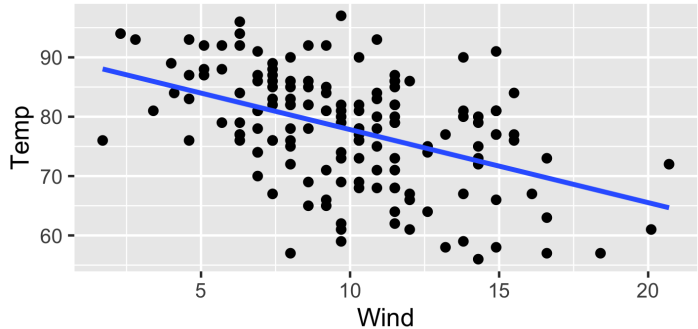
Simple linear regression in R

A **linear regression model** (or just *regression line*) is a line that fits a the data in a scatterplot as closely as possible.

A **linear regression model** (or just *regression line*) is a line that fits a the data in a scatterplot as closely as possible. Here's an example using R's built-in `airquality` data set.



A **linear regression model** (or just *regression line*) is a line that fits a the data in a scatterplot as closely as possible. Here's an example using R's built-in `airquality` data set.



Remember, a regression model like this is only appropriate if the data has an approximately linear shape. If it doesn't, then other techniques are needed.

Use R to answer the following questions about the `airquality` data set, using `Wind` as the explanatory variable and `Temp` as the response variable.

1. Find the equation of the regression line.

2. Use this equation to predict the temperature on a day when the observed wind speed is 8 mph.

3. Determine the residual of the observation in this set with a wind speed of 8 mph and a temperature of 72° Fahrenheit.
